

**Genes And Polynucleotides Associated With Ultraviolet  
Radiation-Mediated Skin Damage And Uses Thereof**

This application claims priority from provisional application Serial No. 60/155,029, filed September 20, 1999, which is incorporated herein by reference in its entirety.

5

**1. Field of the Invention**

The invention provides novel polynucleotides, and their encoded gene products, that are expressed in skin cells, particularly keratinocytes, and methods of using the same. Specifically, the present invention relates to novel protein kinases that are c-Jun N-terminal kinase kinase kinases (JNKKKs). In addition, the invention provides methods of using the novel polynucleotides and their encoded products in drug discovery, particularly in screening for drugs that can reduce ultraviolet light-induced damage of the skin, inflammation and psoriasis, and drugs that can enhance wound healing.

10

**2. Background of the Invention**

Many extracellular signals, such as light, growth factors, cytokines and chemical or physical stresses, activate multi-tiered kinase cascades in the cytoplasm of cells. For example, a growth factor such as epidermal growth factor (EGF) will bind to its cognate receptor on the cell surface, thereby activating the intercellular protein ras, which is associated with the cytoplasmic portion of the cell surface receptor. Ras phosphorylates and thereby activates raf1, a mitogen-activated protein kinase kinase kinase (MAPKKK). Raf1 then induces (also by phosphorylation) the activation of mitogen-activated protein kinase kinases (MEKs), which in turn phosphorylate extracellular signal regulated kinases (ERKs). When phosphorylated, ERKs translocate to the nucleus where they phosphorylate and thus activate transcription factors such as stress activated protein kinase 1 (SAP1) and ternary complex factor Elk1. See, e.g., Fanger et al., 1997, Current Opin. Genet. Dev. 7:67-74.

15

20

25

Stress (such as heat and ultraviolet (UV) light) and cytokines (such as TNF- and IL-1) activate their own sets of kinase-kinase-kinases, termed JNKKKs. These, in turn, act on specific JNKs, which activate c-Jun-N terminal kinase (JNK) and p38. The last two kinases enter the nucleus, where they phosphorylate and activate transcription factors. See, e.g., Diene et al., 1997, PNAS 94:9687-92.

30

Most of the initial events in the cellular responses to different stresses have not been elucidated so far. However, it is clear that different extracellular signals activate different members of the JNKKK family. Thus, some JNKKKs are specifically responsive to TNF- $\alpha$ , others to osmotic shock, yet others to UV illumination. Diene et al., 1997, above; Raingeaud et al., 1995, J. Biol. Chem. 270:7420-6.

35

Skin cells such as keratinocytes are particularly susceptible to ultraviolet radiation damage. However, very little is known about how keratinocytes respond to ultraviolet radiation stress. Manipulation of keratinocyte responses to environmental stress could result

in therapies for a wide variety of skin disorders, as well as cosmetic uses.

Therefore, there is a great need in the art to elucidate the components involved in keratinocyte signal transduction that can be used as targets for drug screening. Accordingly, this invention provides several novel JNKKKs expressed by keratinocytes and involved in the cellular response to ultraviolet radiation, and uses thereof.

### 3. Summary of the Invention

The present invention relates to polynucleotide molecules having nucleotide sequences that encode portions of several novel JNKKK gene products including an MLK4 kinase, a PAK4 kinase, a PAK5 kinase, and a YSK2 kinase, as well as the amino acid sequences encoded by these polynucleotide sequences. The present invention further relates to polynucleotide molecules having nucleotide sequences that encode a PAK5 kinase.

In one aspect, the invention provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human MLK4 gene product. In a preferred embodiment, the portion of the MLK4 gene product comprises the amino acid sequence of SEQ ID NO:2. In a non-limiting embodiment, the isolated polynucleotide molecule of the present invention comprises the nucleotide sequence of SEQ ID NO:1.

The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:1. The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:2.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned MLK4-related polynucleotide molecules of the present invention. In a preferred embodiment, the substantial portion of the MLK4-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human MLK4 gene product or MLK4-related homologous polypeptide of the present invention. In a specific though non-limiting embodiment, the present invention provides a polynucleotide molecule consisting of a nucleotide sequence encoding a peptide fragment consisting of a sub-sequence of the amino acid sequence of SEQ ID NO:2.

In another aspect, the invention provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human PAK4 gene. In a preferred embodiment, the portion of the PAK4 gene product comprises the amino acid sequence of SEQ ID NO:4. In a non-limiting embodiment, the isolated polynucleotide molecule of the present invention comprises the nucleotide sequence of SEQ ID NO:3.

The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID

NO:3. The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:4.

5 The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned PAK4-related polynucleotide molecules of the present invention. In a preferred embodiment, the substantial portion of the PAK4-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human PAK4 gene product or PAK4-related homologous polypeptide of the present invention. In a specific though non-limiting  
10 embodiment, the present invention provides a polynucleotide molecule consisting of a nucleotide sequence encoding a peptide fragment consisting of a sub-sequence of the amino acid sequence of SEQ ID NO:4.

In another aspect, the invention provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human PAK5 gene product. In a  
15 preferred embodiment, the portion of the PAK5 gene product comprises the amino acid sequence of SEQ ID NO:6. In a non-limiting embodiment, the isolated polynucleotide molecule encoding the amino acid sequence of SEQ ID NO:6 comprises the nucleotide sequence of SEQ ID NO:5.

In another aspect, invention provides an isolated polynucleotide molecule comprising  
20 a portion of the nucleotide sequence of the human PAK5 gene, which portion encodes a polypeptide comprising the amino acid sequence of SEQ ID NO:8. In a non-limiting embodiment, the isolated polynucleotide molecule encoding the amino acid sequence of SEQ ID NO:8 comprises the nucleotide sequence of SEQ ID NO:7.

The present invention further provides an isolated polynucleotide molecule that is  
25 homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:5 or SEQ ID NO:7. The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:6 or SEQ ID NO:8.

In another aspect, the invention provides an isolated polynucleotide molecule  
30 comprising a nucleotide sequence encoding the complete human PAK5 gene product having the amino acid sequence of SEQ ID NO:10. In a preferred embodiment, the polynucleotide molecule comprises the nucleotide sequence of SEQ ID NO:9 from nt 199 to nt 2244, which represents the ORF of the cDNA. In another non-limiting embodiment, the isolated polynucleotide molecule encoding the complete human PAK5 gene product comprises the  
35 nucleotide sequence of the ORF of SEQ ID NO:11 from nt 6125 to nt 17,433.

The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID

NO:9 or SEQ ID NO:11.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned PAK5-related polynucleotide molecules of the present invention. In a preferred embodiment, the  
5 substantial portion of the PAK5-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human PAK5 gene product or PAK5-related homologous polypeptide of the present invention.

In another aspect, the invention provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human YSK2 gene product. In a  
10 preferred embodiment, the portion of the YSK2 gene product comprises the amino acid sequence of SEQ ID NO:13. In a non-limiting embodiment, the isolated polynucleotide molecule of the present invention comprises the nucleotide sequence of SEQ ID NO:12.

The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID  
15 NO:12. The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:13.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned YSK2-related polynucleotide molecules of the present invention. In a preferred embodiment, the  
20 substantial portion of the YSK2-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human YSK2 gene product or YSK2-related homologous polypeptide of the present invention. In a specific though non-limiting embodiment, the present invention provides a polynucleotide molecule consisting of a  
25 nucleotide sequence encoding a peptide fragment consisting of a sub-sequence of the amino acid sequence of SEQ ID NO:13.

The present invention further provides compositions and methods for cloning and expressing any of the polynucleotide molecules of the present invention, including cloning  
30 vectors and expression vectors comprising any of the polynucleotide molecules of the present invention, as well as transformed host cells and novel strains or cell lines derived therefrom comprising any of the polynucleotide molecules, cloning vectors or expression vectors of the present invention. In a non-limiting embodiment, the present invention provides a recombinant expression vector comprising a polynucleotide molecule of the present invention in operative association with one or more regulatory elements for expression of the  
35 polynucleotide molecule.

Also provided by the present invention is a substantially purified or isolated polypeptide encoded by a polynucleotide molecule of the present invention. In a specific

though non-limiting embodiment, the polypeptide is a portion of a human MLK4 gene product comprising the amino acid sequence of SEQ ID NO:2. In another specific though non-limiting embodiment, the polypeptide is a portion of a human PAK4 gene product comprising the amino acid sequence of SEQ ID NO:4. In another specific though non-limiting embodiment, the polypeptide is a portion of a human PAK5 gene product, comprising the amino acid sequence of either SEQ ID NO:6 or SEQ ID NO:8, or is the entire human PAK5 gene product comprising the amino acid sequence of SEQ ID NO:10. In another specific though non-limiting embodiment, the polypeptide is a portion of a YSK2 gene product, comprising the amino acid sequence of SEQ ID NO:13.

The present invention also provides substantially purified or isolated polypeptides that are homologous to the portions of the human MLK4, PAK 4, PAK5 and YSK2 gene products of the present invention. The present invention also provides a substantially purified or isolated polypeptide that is homologous to the complete human PAK5 gene product of the present invention. The present invention further provides substantially purified or isolated peptide fragments of the MLK4, PAK4, and PAK5 gene products of the present invention, and substantially purified or isolated peptide fragments of the YSK2 gene product of the present invention that have the first six amino acids of SEQ ID NO:13.

The present invention also provides a method of preparing a substantially purified or isolated portion of a human MLK4, PAK4, PAK5 or YSK2 gene product, or a substantially purified or isolated human PAK5 gene product, or a homologous peptide, or peptide fragment of the present invention, comprising culturing host cells transformed with a polynucleotide molecule or vector of the present invention under conditions conducive to the expression therefrom of the polypeptide or peptide fragment of the invention, and recovering the polypeptide or peptide fragment in substantially purified or isolated form from the cell culture.

Also provided are antibodies specific for the MLK4, PAK4, PAK5 or YSK2 gene product, homologous peptide, or peptide fragment of the present invention, and methods of detecting the MLK4, PAK4, PAK5 or YSK2 gene product, homologous peptide, or peptide fragment of the present invention in a sample. Still another aspect of the invention provides methods of identifying compounds that bind to the MLK4, PAK4, PAK5 or YSK2 gene product, homologous peptide, or peptide fragment of the present invention.

The present invention also provides methods of detecting an MLK4, PAK4, PAK5 or YSK2-related polynucleotide in a sample, comprising contacting the sample with a compound that binds to and forms a complex with the particular polynucleotide for a period of time sufficient to form the complex, and detecting the complex, so that if a complex is detected, the MLK4, PAK4, PAK5 or YSK2-related polynucleotide, respectively, is detected. In a non-limiting embodiment, the method comprises contacting the sample under stringent hybridization conditions with nucleic acid primers that anneal to the particular polynucleotide

under such hybridization conditions, and amplifying the annealed polynucleotides, so that if a particular polynucleotide is amplified, the MLK4, PAK4, PAK5 or YSK2-related polynucleotide, respectively, is detected.

5 The invention further provides a method of screening for compounds that affect the cellular levels of a JNKKK gene product, comprising: (a) applying a test compound to a test sample; (b) determining the cellular levels of at least one gene product in the test sample, wherein the gene product is from a gene comprising a nucleotide sequence selected from the group consisting of SEQ ID NOS: 1, 3, 5, 7, 9, 11 and 12; and (c) comparing the levels of the gene product in the test sample with that in a reference sample; wherein a specific change in  
10 the cellular levels of the gene product in the test sample as compared to the reference sample indicates that the test compound affects the cellular levels of gene product from a JNKKK gene. In a preferred embodiment, the method further comprises the step of applying a stress event to the test sample and determining the effect of the test compound on the response of the test sample to the stress event.

15 The invention further provides a method of screening for compounds that affect the expression of a gene that encodes a JNKKK gene product, comprising: (a) applying a test compound to a test sample; (b) determining the expression level of at least one gene in cells of the test sample, wherein the gene comprises a nucleotide sequence selected from the group consisting of SEQ ID NOS: 1, 3, 5, 7, 9, 11 and 12; and (c) comparing the expression  
20 level of the gene in the test sample with that in a reference sample; wherein a specific change in the expression of the gene in the test sample as compared to the reference sample indicates that the test compound affects the expression of the gene. In a preferred embodiment, the method further comprises the step of applying a stress event to the test sample and determining the effect of the test compound on the gene expression response of  
25 the test sample to the stress event.

Still another aspect of the invention provides a method of screening for compounds that affect the activity of a JNKKK gene product, the method comprising: (a) applying a test compound to a test sample; and (b) determining the activity of a JNKKK gene product in the test sample versus a reference sample, wherein the JNKKK gene product comprises an  
30 amino acid sequence selected from the group consisting of: SEQ ID NOS: 2, 4, 6, 8, 10 and 13; wherein a test compound that alters the JNKKK gene product activity in the test sample as compared to the reference sample is identified as a compound that affects the activity of the JNKKK gene product. In a preferred embodiment, the method further comprises the step of applying a stress event to the test sample and determining the effect of the test compound  
35 on the response of the test sample to the stress event.

#### **4. Brief Description of the Figures**

Figure 1 is a schematic diagram illustrating the structure of the PAK5 gene.

Figure 2 is a Northern Blot illustrating the tissue-specific expression of MLK4, PAK4 and PAK5 genes. Messenger RNA was isolated from heart, brain, placenta, lung, liver, skeletal muscle, kidney and pancreas, run on a denaturing gel in the indicated lanes, and blotted to a membrane. The same blot was sequentially hybridized (after stripping between

5 hybridizations) to labeled 150 base pair probes specific for MLK4, PAK4 and PAK5.

Figure 3 shows the induction of YSK2 and PAK5 genes in response to ultraviolet radiation. Figure 3A is a Northern blot of mRNA from keratinocytes untreated (control) or treated (control) with UV-C radiation for 5 days. The blot was hybridized to a 150 base pair probe specific for the YSK2 gene. Figure 3B shows a differential display experiment

10 designed to examine any change in expression levels of the PAK4 and PAK5 genes in response to UV-A light. Keratinocytes were exposed to UV-A light for 0, 6 or 24 hours, harvested and mRNA analyzed. Bands corresponding the PAK4 and PAK5 message are indicated.

#### **5. Detailed Description of the Invention**

15 The present invention relates to identification and characterization of polynucleotide molecules expressed in skin keratinocytes, which polynucleotide molecules encode JNKKK polypeptides. Because the kinase domains of JNKKKs are conserved in sequence, primers can be designed for reverse transcription-polymerase chain reaction (RT-PCR) detection of virtually all the JNKKKs expressed by a cell or cell type. In one embodiment, the primer pair

20 5'-ATGCA(CA)CANGA(CT)AT(ACT)AA(AG)-3' (SEQ ID NO:14) (forward) and 5'-GCNAC(CT)TCNGGNGCCATCCA-3' (SEQ ID NO:15) (reverse) can be used to detect novel JNKKKs. The product of using the primer pair is a common 150 bp segment. As discussed below in the Example sections, a primer pair was used to screen human epidermal keratinocyte mRNA, and polynucleotides encoding several novel JNKKKs were discovered.

25 In addition, the present invention relates to the discovery that the JNKKKs encoded by these polynucleotides are involved in the cellular response to stress such as ultraviolet (UV) light. By way of example, the invention is described in the sections below for an isolated polynucleotide molecule comprising the nucleotide sequence of a portion of the MLK4 open reading frame (ORF) (SEQ ID NO:1); for an isolated polynucleotide molecule comprising the

30 nucleotide sequence of a portion of the PAK4 ORF (SEQ ID NO:3); for an isolated polynucleotide molecule comprising the nucleotide sequence of a portion of the PAK5 ORF (SEQ ID NO:5); for another isolated polynucleotide molecule comprising the nucleotide sequence of a portion of the PAK5 gene (SEQ ID NO:7); for an isolated polynucleotide molecule comprising the nucleotide sequence of the cDNA encoding the PAK5 gene product

35 (SEQ ID NO:9, ORF from nt 199-2244); for an isolated polynucleotide molecule comprising the nucleotide sequence of the PAK5 gene (SEQ ID NO:11, ORF from nt 6125-17433); and for an isolated polynucleotide molecule comprising the nucleotide sequence of a portion of the

YSK2 ORF (SEQ ID NO:12).

### **5.1. Polynucleotide Molecules**

As used herein, the terms "polynucleotide molecule," "polynucleotide sequence," "coding sequence" "open-reading frame (ORF)", and the like, are intended to refer to both  
5 DNA and RNA molecules, which can either be single-stranded or double-stranded. A coding sequence or ORF can include but is not limited to prokaryotic sequences, cDNA sequences, genomic DNA sequences, and chemically synthesized DNA and RNA sequences. A "gene product" is intended to refer to a product encoded by a gene, including the transcribed RNA message (including exons and introns), the spliced messenger RNA (mRNA), and the  
10 translated protein product encoded by the respective mRNA.

Production and manipulation of the polynucleotide molecules and oligonucleotide molecules disclosed herein are within the skill in the art and can be carried out according to recombinant techniques described, among other places, in Maniatis et al. 1989, Molecular Cloning, A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor,  
15 NY; Ausubel et al., 1989, Greene Publishing Associates & Wiley Interscience, NY; Sambrook et al., 1989, Molecular Cloning: A Laboratory Manual, 2d ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY; Innis et al. (eds), 1995, PCR Strategies, Academic Press, Inc., San Diego; and Erlich (ed), 1992, PCR Technology, Oxford University Press, New York, all of which are incorporated herein by reference.

#### **20 5.1.1. MLK4-related Polynucleotide Molecules**

The present invention provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human MLK4-related gene product. In a preferred embodiment, the portion of the MLK4 gene product comprises the amino acid sequence of SEQ ID NO:2. In a non-limiting embodiment, the isolated polynucleotide  
25 molecule of the present invention comprises the nucleotide sequence of SEQ ID NO:1.

The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:1. The term "homologous" when used in this respect means a polynucleotide molecule comprising a nucleotide sequence: (a) that encodes the same polypeptide as encoded by  
30 SEQ ID NO:1, but that includes one or more silent changes to the nucleotide sequence according to the degeneracy of the genetic code (i.e., a degenerate variant); or (b) that has at least about 70%, more preferably at least about 80%, and most preferably at least about 90% nucleotide sequence identity to the nucleotide sequence of SEQ ID NO:1, as determined by any standard nucleotide sequence identity algorithm such as BLASTN (GENBANK), and  
35 which hybridizes to the complement of a polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide comprising the amino acid sequence of SEQ ID NO:2 under moderately stringent conditions, i.e., hybridization to filter-bound DNA in 0.5 M

NaHPO<sub>4</sub>, 7% sodium dodecyl sulfate (SDS), 1 mM EDTA at 65°C, and washing in 0.2XSSC/0.1% SDS at 42°C (see Ausubel et al. (eds.), 1989, Current Protocols in Molecular Biology, Vol. I, Green Publishing Associates, Inc., and John Wiley & Sons, Inc., New York, at p. 2.10.3), and is useful in practicing the invention. In a preferred embodiment, the  
5 homologous polynucleotide molecule hybridizes to the complement of a polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide comprising the amino acid sequence of SEQ ID NO:2 under highly stringent conditions, i.e., hybridization to filter-bound DNA in 0.5 M NaHPO<sub>4</sub>, 7% SDS, 1 mM EDTA at 65°C, and washing in 0.1 x SSC/0.1% SDS at 68°C (Ausubel et al., 1989, above), and is useful in practicing the  
10 invention. In a more preferred embodiment, the homologous polynucleotide molecule hybridizes under highly stringent conditions to the complement of a polynucleotide molecule consisting of the nucleotide sequence of SEQ ID NO:1, and is useful in practicing the invention.

As used herein, an MLK4-related polynucleotide molecule is "useful in practicing the  
15 invention" where the polynucleotide molecule: (i) encodes a peptide that can be used to generate antibodies that immunospecifically recognize the MLK4 gene product from a eukaryotic cell; or (ii) can detect the presence of the MLK4 transcript in a test sample; or (iii) can enable a method for altering the regulation or expression of the endogenous MLK4 gene (such as by gene activation or inactivation techniques, e.g., insertion of a transcriptional  
20 activator sequence into an intron, or deletion of one or more exons); or (iv) can be used to amplify a polynucleotide molecule comprising the nucleotide sequence of the MLK4 ORF in a eukaryotic cell using standard amplification techniques such as PCR. Such homologous polynucleotide molecules can include naturally occurring MLK4 genes present in eukaryotic species other than humans (and particularly in mammalian species, such as, for example,  
25 mouse, cow, sheep, guinea pig and rat), or in other human isolates, as well as mutated MLK4 alleles, whether naturally occurring, chemically synthesized, or genetically engineered.

The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:2. As used herein to  
30 refer to polypeptides having amino acid sequences that are homologous to the amino acid sequence of a portion of an MLK4 gene product from a human, the term "homologous" means a polypeptide comprising the amino acid sequence of SEQ ID NO:2, but in which one or more amino acid residues thereof has been conservatively substituted with a different amino acid residue, wherein the resulting amino acid sequence has at least about 70%, more preferably  
35 at least about 80%, and most preferably at least about 90% sequence identity to SEQ ID NO:2 wherein amino acid sequence identity is determined by any standard amino acid sequence identity algorithm, such as, e.g., BLASTP (GENBANK), where the resulting

polypeptide is useful in practicing the invention. Conservative amino acid substitutions are well known in the art. Rules for making such substitutions include those described by Dayhof, M.D., 1978, Nat. Biomed. Res. Found., Washington, D.C., Vol. 5, Sup. 3, among others. More specifically, conservative amino acid substitutions are those that generally take place within a family of amino acids that are related in the acidity, or polarity of their side chains. Genetically encoded amino acids are generally divided into four groups: (1) acidic = aspartate, glutamate; (2) basic = lysine, arginine, histidine; (3) non-polar = alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan; and (4) uncharged polar = glycine, asparagine, glutamine, cysteine, serine, threonine, tyrosine. Phenylalanine, tryptophan and tyrosine are also jointly classified as aromatic amino acids. One or more replacements within any particular group, e.g., of a leucine with an isoleucine or valine, or of an aspartate with a glutamate, or of a threonine with a serine, or of any other amino acid residue with a structurally related amino acid residue, e.g., an amino acid residue with similar acidity, or polarity or with similarity in a combination thereof, will generally have an insignificant effect on the function of the polypeptide.

As used herein, an MLK4-related polypeptide is "useful in practicing the invention" where the polypeptide can be used to raise antibodies against an MLK4 gene product from a eukaryotic, preferably mammalian, and most preferably human cell or tissue, or to screen for compounds that modulate MLK4 activity or production in such a cell or tissue.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned MLK4-related polynucleotide molecules of the present invention. As used herein, a "substantial portion" of an MLK4-related polynucleotide molecule means a polynucleotide molecule consisting of less than the full length of the nucleotide sequence of SEQ ID NO:1 or homologous polynucleotide molecule thereof, but comprising at least about 20%, and more preferably at least about 30%, of the length of said nucleotide sequence, and that is useful in practicing the invention, as usefulness is defined above for MLK4-related polynucleotide molecules. In a non-limiting embodiment, the substantial portion of the MLK4-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human MLK4 gene product of the present invention. A "peptide fragment" of an MLK4-related polypeptide refers to a polypeptide consisting of a sub-sequence of SEQ ID NO:2, which sub-sequence is useful in practicing the invention, as usefulness is defined above for MLK4-related polypeptides. As used herein, a "peptide fragment" is preferably at least about 15 amino acid residues, and more preferably at least about 30 amino acid residues in length.

The MLK4-related polynucleotide molecules disclosed herein can be used to express a portion of the human MLK4 gene product, to detect expression of an MLK4 gene product in a cell type or tissue, to prepare novel cell lines in which the MLK4 gene has been mutated (for

example, altered or removed by homologous recombination), to create and express a dominant-negative MLK4, e.g., by mutating the ATP binding site, using well known techniques (see, e.g., Abo et al., below), and to identify MLK4 homolog genes in eukaryotic species other than humans, and particularly in other mammalian species, using known techniques. Thus, the present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding an MLK4 homolog gene product. As used herein, an "MLK4 homolog gene product" is defined as a gene product encoded by an MLK4 homolog gene which, in turn, is defined as a gene from a different eukaryotic species other than human and which is recognized by those of skill in the art as a homolog of the human MLK4 gene based on a degree of sequence identity at the amino acid level of greater than about 70%.

Methods for identifying polynucleotide clones containing MLK4 homolog genes are known in the art. For example, a polynucleotide molecule comprising a portion of the human MLK4 ORF can be detectably labeled and used to screen a genomic library constructed from DNA derived from the organism of interest. The stringency of the hybridization conditions can be selected based on the relationship of the reference organism to the organism of interest. Requirements for different stringency conditions are well known to those of skill in the art, and such conditions will vary predictably depending on the specific organisms from which the library and the labeled sequences are derived. Genomic DNA libraries can be screened for MLK4 homolog gene coding sequences using the techniques set forth, among other places, in Benton and Davis, 1977, Science 196:180, for bacteriophage libraries, and in Grunstein and Hogness, 1975, Proc. Natl. Acad. Sci. USA, 72:3961-3965, for plasmid libraries, which publications are incorporated herein by reference. Polynucleotide molecules having nucleotide sequences known to include a portion of the MLK4 ORF, as shown in SEQ ID NO:1, or oligonucleotide molecules representing portions thereof, can be used as probes in these screening experiments. Alternatively, oligonucleotide probes can be synthesized that correspond to nucleotide sequences deduced from the amino acid sequence of the purified MLK4 gene product.

Clones identified as containing MLK4 homolog gene coding sequences can be tested for appropriate biological function. For example, the clones can be subjected to sequence analysis in order to identify a suitable reading frame, as well as initiation and termination signals. The cloned DNA sequence can then be inserted into an appropriate expression vector which is then transformed into cells (such as human cells) that have been rendered MLK4 null to test for complementation. Transformed host cells can then be analyzed for MLK4 signal transduction.

#### **5.1.2. PAK4-related Polynucleotide Molecules**

The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human PAK4 gene product. In a

preferred embodiment, the portion of the PAK4 gene product comprises the amino acid sequence of SEQ ID NO:4. In a non-limiting embodiment, the isolated polynucleotide molecule of the present invention comprises the nucleotide sequence of SEQ ID NO:3.

The present invention further provides an isolated polynucleotide molecule that is  
5 homologous to a polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:3. The term "homologous" when used in this respect means a polynucleotide molecule comprising a nucleotide sequence: (a) that encodes the same polypeptide as encoded by SEQ ID NO:3, but that includes one or more silent changes to the nucleotide sequence according to the degeneracy of the genetic code; or (b) that has at least about 70%, more  
10 preferably at least about 80%, and most preferably at least about 90% nucleotide sequence identity to the nucleotide sequence of SEQ ID NO:3, as determined by any standard nucleotide sequence identity algorithm such as BLASTN (GENBANK) and hybridizes to the complement of a polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide comprising the amino acid sequence of SEQ ID NO:4 under moderately stringent conditions, i.e., hybridization to filter-bound DNA in 0.5 M NaHPO<sub>4</sub>, 7% SDS, 1 mM EDTA at  
15 65°C, and washing in 0.2xSSC/0.1% SDS at 42°C (Ausubel et al., 1989, above), and is useful in practicing the invention. In a preferred embodiment, the homologous polynucleotide molecule hybridizes to the complement of a polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide comprising the amino acid sequence of SEQ ID NO:4 under highly stringent conditions, i.e., hybridization to filter-bound DNA in 0.5 M NaHPO<sub>4</sub>, 7%  
20 SDS, 1 mM EDTA at 65°C, and washing in 0.1xSSC/0.1 % SDS at 68°C (Ausubel et al., 1989, above), and is useful in practicing the invention. In a more preferred embodiment, the homologous polynucleotide molecule hybridizes under highly stringent conditions to the complement of a polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:3, and is useful in practicing the invention.  
25

As used herein, a PAK4-related polynucleotide molecule is "useful in practicing the invention" where the polynucleotide molecule: (i) encodes a peptide that can be used to generate antibodies that immunospecifically recognize the PAK4 gene product from a eukaryotic cell; or (ii) can detect the presence of the PAK4 transcript in a test sample; or (iii)  
30 can enable a method for altering the regulation or expression of the endogenous PAK4 gene (such as by gene activation or inactivation techniques, e.g., insertion of a transcriptional activator sequence into an intron, or deletion of one or more exons); or (iv) can be used to amplify a polynucleotide molecule comprising the nucleotide sequence of the PAK4 ORF in a eukaryotic cell using standard amplification techniques such as PCR. Such homologous  
35 polynucleotide molecules can include naturally occurring PAK4 genes present in eukaryotic species other than humans (and particularly in mammalian species, such as, for example, mouse, cow, sheep, guinea pig and rat), or in other human isolates, as well as mutated PAK4

alleles, whether naturally occurring, chemically synthesized, or genetically engineered.

The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:4. As used herein to refer to polypeptides having amino acid sequences that are homologous to the amino acid sequence of a PAK4 gene product from a human cell, the term "homologous" means a polypeptide comprising the amino acid sequence of SEQ ID NO:4, but in which one or more amino acid residues thereof has been conservatively substituted with a different amino acid residue, as conservative amino acid substitutions are defined above, wherein the resulting amino acid sequence has at least about 70%, more preferably at least about 80%, and most preferably at least about 90% sequence identity to SEQ ID NO:4, as determined, e.g., using the BLASTP algorithm (GENBANK), where the resulting polypeptide is useful in practicing the invention.

As used herein, a PAK4-related polypeptide is "useful in practicing the invention" where the polypeptide can be used to raise antibodies against a PAK4 gene product from a eukaryotic, preferably mammalian, and most preferably human, cell or tissue, or to screen for compounds that modulate PAK4 activity or production in such a cell or tissue.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned PAK4-related polynucleotide molecules of the present invention. As used herein, a "substantial portion" of a PAK4-related polynucleotide molecule means a polynucleotide molecule consisting of less than the full length of SEQ ID NO:3 or homologous polynucleotide molecule thereof, but comprising at least about 20%, and more preferably at least about 30%, of the length of said nucleotide sequence, and that is useful in practicing the invention, as usefulness is defined above for PAK4-related polynucleotide molecules. In a non-limiting embodiment, the substantial portion of the PAK4-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human PAK4 gene product of the present invention. A "peptide fragment" of a PAK4-related polypeptide refers to a polypeptide consisting of a sub-sequence of SEQ ID NO:4, which sub-sequence is useful in practicing the invention, as usefulness is defined above for PAK4-related polypeptides. Peptide fragments of the invention are preferably at least about 15 amino acid residues, and more preferably at least about 30 amino acid residues in length.

The PAK4-related polynucleotide molecules disclosed herein can be used to express a portion of the human PAK4 gene product, to detect expression of a PAK4 gene product in a cell type or tissue, to prepare novel cell lines in which the PAK4 gene has been mutated (for example, altered or removed by homologous recombination), to create and express a dominant-negative PAK4, e.g., by mutating the ATP binding site, using well known techniques

(see, e.g., Abo et al., below), and to identify PAK4 homolog genes in eukaryotic species other than humans, and particularly in other mammalian species, using known techniques. Thus, the present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a PAK4 homolog gene product. As used herein, a “PAK4 homolog gene product” is defined as a gene product encoded by a PAK4 homolog gene which, in turn, is defined as a gene from a different eukaryotic species other than human and which is recognized by those of skill in the art as a homolog of the human PAK4 gene based on a degree of sequence identity at the amino acid level of greater than about 70%. Methods for identifying polynucleotide clones containing PAK4 homolog genes are known in the art as described above.

#### **5.1.3. PAK5-related Polynucleotide Molecules**

The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a human PAK5 gene product. In a preferred embodiment, the portion of the PAK5 gene product comprises the amino acid sequence of SEQ ID NO:6. In a non-limiting embodiment, the isolated polynucleotide molecule encoding the amino acid sequence of SEQ ID NO:6 comprises the nucleotide sequence of SEQ ID NO:5. In another preferred embodiment, the portion of the PAK5 gene product comprises the amino acid sequence of SEQ ID NO:8. In a non-limiting embodiment, the isolated polynucleotide molecule encoding the amino acid sequence of SEQ ID NO:8 comprises the nucleotide sequence of SEQ ID NO:7. Still another non-limiting embodiment of the invention is the sequence of any one of the exons of the PAK5 genomic DNA (see SEQ ID NO:7). A further non-limiting embodiment of the invention is the sequence of any one of the introns of the PAK5 genomic DNA.

The present invention further provides an isolated polynucleotide molecule comprising the cDNA nucleotide sequence of SEQ ID NO:9 (ORF from nt 199-2244) encoding a complete human PAK5 gene product. The present invention further provides an isolated polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:11 (ORF from nt 6125-17433), which represents the human PAK5 gene.

The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising a nucleotide sequence encoding a portion of a PAK5 gene product of the present invention. The term “homologous” when used in this respect means a polynucleotide molecule comprising a nucleotide sequence: (a) that encodes the same polypeptide as encoded by SEQ ID NO:5, SEQ ID NO:7, SEQ ID NO:9 or SEQ ID NO:11, but that includes one or more silent changes to the nucleotide sequence according to the degeneracy of the genetic code; or (b) that has at least about 70%, more preferably at least about 80%, and most preferably at least about 90% nucleotide sequence identity to the nucleotide sequence of SEQ ID NO:5 or SEQ ID NO:7, or to the ORF of SEQ

5

20

30

35

amino acid substitutions are defined above, wherein the resulting amino acid sequence has at least about 70%, more preferably at least about 80%, and most preferably at least about 90% sequence identity to SEQ ID NO:6, SEQ ID NO:8 or SEQ ID NO:10, as determined, e.g., using the BLASTP algorithm (GENBANK), and where the resulting polypeptide is useful in practicing the invention.

As used herein, a PAK5-related polypeptide is "useful in practicing the invention" where the polypeptide can be used to raise antibodies against a PAK5 gene product from a eukaryotic, preferably mammalian, and most preferably human, cell or tissue, or to screen for compounds that modulate PAK5 activity or production in such a cell.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned PAK5-related polynucleotide molecules of the present invention. As used herein, a "substantial portion" of a PAK5-related polynucleotide molecule means a polynucleotide molecule consisting of less than the full length of SEQ ID NO:5, SEQ ID NO:7, SEQ ID NO:9 (from nt 199-2244) or SEQ ID NO:11 (from nt 6125-17433) or homologous polynucleotide molecule thereof, but comprising at least about 20%, and more preferably at least about 30%, the length of said nucleotide sequence, and that is useful in practicing the invention, as usefulness is defined above for PAK5-related polynucleotide molecules. In a non-limiting embodiment, the substantial portion of the PAK5-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a human PAK5 gene product of the present invention. A "peptide fragment" of a PAK5-related polypeptide refers to a polypeptide consisting of a sub-sequence of SEQ ID NO:6, SEQ ID NO:8 or SEQ ID NO:10, which sub-sequence is useful in practicing the invention, as usefulness is defined above for PAK5-related polypeptides. Peptide fragments of the invention are preferably at least about 15 amino acid residues, and more preferably at least about 30 amino acid residues in length.

The PAK5-related polynucleotide molecules disclosed herein can be used to express a portion of the PAK5 gene product, to detect expression of a PAK5 gene in a cell or tissue, to prepare novel cell lines in which the PAK5 gene has been mutated (for example, altered or removed by homologous recombination), to create and express a dominant-negative PAK5 by mutating the ATP binding site using well known techniques (see, e.g., Abo et al., below), and to identify PAK5 homolog genes in other eukaryotic species or cell types using standard techniques. Thus, the present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a PAK5 homolog gene product. As used herein, a "PAK5 homolog gene product" is defined as a gene product encoded by a PAK5 homolog gene which, in turn, is defined as a gene from a eukaryotic species other than human, and which is recognized by those of skill in the art as a homolog of the human PAK5 gene based on a degree of sequence identity at the amino acid level of greater than about 80%. Methods

for identifying polynucleotide clones containing PAK5 homolog genes are known in the art, as described above.

#### **5.1.4. YSK2-related Polynucleotide Molecules**

5 The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence encoding a portion of a YSK2 gene product from a human cell. In a preferred embodiment, the YSK2 gene product comprises the amino acid sequence of SEQ ID NO:13. In a non-limiting embodiment, the isolated polynucleotide molecule of the present invention comprises the nucleotide sequence of SEQ ID NO:12.

10 The present invention further provides an isolated polynucleotide molecule that is homologous to a polynucleotide molecule comprising a nucleotide sequence encoding a portion of the YSK2 gene product of the present invention. The term "homologous" when used in this respect means a polynucleotide molecule comprising a nucleotide sequence: (a) that encodes the same polypeptide as encoded by SEQ ID NO:12, but that includes one or more silent changes to the nucleotide sequence according to the degeneracy of the genetic  
15 code; or (b) that has at least about 70%, more preferably at least about 80%, and most preferably at least about 90% nucleotide sequence identity to the nucleotide sequence of SEQ ID NO:12, as determined by any standard nucleotide sequence identity algorithm such as BLASTN (GENBANK), and hybridizes to the complement of a polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide comprising the amino acid  
20 sequence of SEQ ID NO:13 under moderately stringent conditions, i.e., hybridization to filter-bound DNA in 0.5 M NaHPO<sub>4</sub>, 7% SDS, 1 mM EDTA at 65°C, and washing in 0.2xSSC/0.1% SDS at 42°C (Ausubel et al., 1989, above), and encodes at least the first 6 amino acid residues of SEQ ID NO:13 and is useful in practicing the invention. In a preferred embodiment, the homologous polynucleotide molecule hybridizes to the complement of a  
25 polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide comprising the amino acid sequence of SEQ ID NO:13 under highly stringent conditions, i.e., hybridization to filter-bound DNA in 0.5 M NaHPO<sub>4</sub>, 7% SDS, 1 mM EDTA at 65°C, and washing in 0.1xSSC/0.1 % SDS at 68°C (Ausubel et al., 1989, above), and encodes at least the first 6 amino acid residues of SEQ ID NO:13, and is useful in practicing the invention. In a  
30 more preferred embodiment, the homologous polynucleotide molecule hybridizes under highly stringent conditions to the complement of a polynucleotide molecule comprising the nucleotide sequence of SEQ ID NO:12, and encodes at least the first 6 amino acid residues of SEQ ID NO:13, and is useful in practicing the invention.

35 As used herein, a YSK2-related polynucleotide molecule is "useful in practicing the invention" where the polynucleotide molecule: (i) encodes a peptide that can be used to generate antibodies that immunospecifically recognize the YSK2 gene product from a eukaryotic cell; or (ii) can detect the presence of the YSK2 transcript in a test sample; or (iii)

can enable a method for altering the regulation or expression of the endogenous YSK2 gene (such as by gene activation or inactivation techniques, e.g., insertion of a transcriptional activator sequence into an intron, or deletion of one or more exons); or (iv) can be used to amplify a polynucleotide molecule comprising the nucleotide sequence of the YSK2 ORF in a eukaryotic cell using standard amplification techniques such as PCR. Such homologous polynucleotide molecules can include naturally occurring YSK2 genes present in eukaryotic species other than humans (and particularly in mammalian species, such as, for example, mouse, cow, sheep, guinea pig and rat), or in other human isolates, as well as mutated YSK2 alleles, whether naturally occurring, chemically synthesized, or genetically engineered.

The present invention further provides an isolated polynucleotide molecule comprising a nucleotide sequence that encodes a polypeptide having an amino acid sequence that is homologous to the amino acid sequence of SEQ ID NO:13. As used herein to refer to polypeptides having amino acid sequences that are homologous to the amino acid sequence of a YSK2 gene product from a human cell, the term "homologous" means a polypeptide comprising the amino acid sequence of SEQ ID NO:13, but in which one or more amino acid residues thereof has been conservatively substituted with a different amino acid residue, as conservative amino acid substitutions are defined above, wherein the resulting amino acid sequence has at least about 70%, more preferably at least about 80%, and most preferably at least about 90% sequence identity to SEQ ID NO:13, as determined, e.g., using the BLASTP algorithm (GENBANK), and which encodes at least the first 6 amino acid residues of SEQ ID NO:13 and where the resulting polypeptide is useful in practicing the invention.

As used herein, a YSK2-related polypeptide is "useful in practicing the invention" where the polypeptide can be used to raise antibodies against a YSK2 gene product from a eukaryotic, preferably mammalian, and most preferably human, cell or tissue, or to screen for compounds that modulate YSK2 activity or production in such a cell or tissue.

The present invention further provides an isolated polynucleotide molecule consisting of a nucleotide sequence that is a substantial portion of any of the aforementioned YSK2-related polynucleotide molecules of the present invention. As used herein, a "substantial portion" of a YSK2-related polynucleotide molecule means a polynucleotide molecule consisting of less than the full length of SEQ ID NO:12 or homologous polynucleotide molecule thereof, but comprising at least about 20%, and more preferably at least about 30%, the length of said nucleotide sequence, and encoding at least the first 6 amino acid residues of SEQ ID NO:13 and that is useful in practicing the invention, as usefulness is defined above for YSK2-related polynucleotide molecules. In a non-limiting embodiment, the substantial portion of the YSK2-related polynucleotide molecule consists of a nucleotide sequence that encodes a peptide fragment of a YSK2 gene product of the present invention. A "peptide

fragment" of a YSK2-related polypeptide refers to a polypeptide consisting of a sub-sequence of the amino acid sequence of SEQ ID NO:13, yet contains the sequence of residues 1 to 6 of SEQ ID NO:13, and which sub-sequence is useful in practicing the invention, as usefulness is defined above for YSK2-related polypeptides. Peptide fragments of the invention are preferably at least about 15 amino acid residues, and more preferably at least about 30 amino acid residues in length.

The YSK2-related polynucleotide molecules disclosed herein can be used to express a portion of the human YSK2 gene product, to detect expression of a YSK2 gene product in a cell type or tissue, to prepare novel cell lines in which the YSK2 gene has been mutated (for example, altered or removed by homologous recombination), to create and express a dominant-negative YSK2 by mutating the ATP binding site using well known techniques (see, e.g., Abo et al., below), and to identify YSK-2 homolog genes in other eukaryotic species or cell types, as described above. As used herein, a "YSK2 homolog gene product" is defined as a gene product encoded by a YSK2 homolog gene which, in turn, is defined as a gene from a eukaryotic species other than human, and which is recognized by those of skill in the art as a homolog of the human YSK2 gene based on a degree of sequence identity at the amino acid level of greater than about 80%. Methods for identifying polynucleotide clones containing YSK2 homolog genes are known in the art, as described above.

## **5.2. Oligonucleotide Molecules**

The present invention further provides oligonucleotide molecules that hybridize to any of the aforementioned polynucleotide molecules of the present invention, or that hybridize to a polynucleotide molecule having a nucleotide sequence that is the complement of any of the aforementioned polynucleotide molecules of the present invention. Such oligonucleotide molecules are preferably at least about 10 nucleotides in length, and more preferably at least about 20 nucleotides in length, and can hybridize to one or more of the aforementioned polynucleotide molecules under moderately or highly stringent conditions. For shorter oligonucleotide molecules, an example of highly stringent conditions includes washing in 6xSSC/0.5% sodium pyrophosphate at about 37°C for ~14-base oligos, at about 48°C for ~17-base oligos, at about 55°C for ~20-base oligos, and at about 60°C for ~23-base oligos. For longer oligonucleotide molecules (i.e., greater than about 100 nts), examples of moderately and highly stringent conditions are described in Section 5.1.1 above for homologous polynucleotide molecules. Hybridization conditions can be appropriately adjusted as known in the art, depending upon the particular oligonucleotide molecules utilized.

In a preferred embodiment, an oligonucleotide molecule of the present invention hybridizes under highly stringent conditions to a polynucleotide molecule having a nucleotide sequence selected from the group consisting of SEQ ID NOs:1, 3, 5, 7, 9, 11 or 12, or to a

polynucleotide molecule having a nucleotide sequence that is the complement of a nucleotide sequence selected from the group consisting of SEQ ID NOs:1, 3, 5, 7, 9, 11 or 12.

The oligonucleotide molecules of the present invention are useful for a variety of purposes, including as primers in amplifying a MLK4, PAK4, PAK5 or YSK2 gene product-  
5 encoding polynucleotide molecule, or as anti-sense molecules useful in regulating expression of JNKKK genes and gene products. Amplification can be carried out using suitably designed oligonucleotide molecules in conjunction with standard techniques, such as the polymerase chain reaction (PCR), although other amplification techniques known in the art, e.g., the  
10 ligase chain reaction, can also be used. For example, for PCR, a mixture comprising suitably designed primers, a template comprising the nucleotide sequence to be amplified, and appropriate PCR enzymes and buffers, is prepared and processed according to standard protocols to amplify a specific MLK4-, PAK4-, PAK5-, or YSK2-related polynucleotide sequence of the template.

### **5.3. Recombinant Expression Systems**

#### **5.3.1. Expression Vectors**

The present invention further provides recombinant cloning vectors and recombinant expression vectors comprising a polynucleotide molecule of the present invention, which vectors are useful in cloning or expressing said polynucleotide molecules, including polynucleotide molecules comprising portions of the MLK4, PAK4, PAK5 or YSK2 ORFs, or  
20 the entire PAK5 ORF, of the present invention.

The following description is intended to apply to all of the aforementioned polynucleotide molecules and polypeptides of the present invention, including polynucleotide molecules comprising portions of the MLK4, PAK4, PAK5 or YSK2 ORFs, the entire PAK5 ORF, and their gene products, and all homologous polynucleotide molecules, homologous  
25 polypeptides, substantial portions of such polynucleotide molecules, and peptide fragments of such gene products and polypeptides, as defined above, unless otherwise indicated.

Recombinant vectors of the present invention, particularly expression vectors, are preferably constructed so that the coding sequence for the polynucleotide molecule of the present invention is in operative association with one or more regulatory elements necessary  
30 for transcription and translation of the coding sequence to produce a polypeptide. As used herein, the term "regulatory element" includes but is not limited to nucleotide sequences of inducible and noninducible promoters, enhancers, operators and other elements known in the art that serve to drive and/or regulate expression of polynucleotide coding sequences. Also, as used herein, the coding sequence is in "operative association" with one or more regulatory  
35 elements where the regulatory elements effectively regulate and allow for the transcription of the coding sequence or the translation of its mRNA, or both.

Typical plasmid vectors that can be engineered to contain a polynucleotide molecule

of the present invention include pCR-Blunt, pCR2.1 (Invitrogen), and pGEM3Zf (Promega), among many others. Additionally, vectors particularly designed for expression in eukaryotic cells, such as mammalian cells, are commercially available from Invitrogen (San Diego, CA) and Promega.

5           The regulatory elements of these vectors can vary in their strength and specificities. Depending on the host/vector system utilized, any of a number of suitable transcription and translation elements can be used. Non-limiting examples of transcriptional regulatory regions or promoters for bacteria include the  $\beta$ -gal promoter, the T7 promoter, the TAC promoter, lambda left and right promoters, trp and lac promoters, and the trp-lac fusion promoters. Non-  
10       limiting examples of transcriptional regulatory regions or promoters for eukaryotic cells include viral regulatory regions such as, for example, the SV40 early promoter region, the herpes thymidine kinase promoter, the cytomegalovirus (CMV) promoter, and the mouse mammary tumor virus control region, tissue specific or inducible promoters from endogenous eukaryotic genes such as, for example, the albumin promoter, myosin light chain-2 promoter, the insulin  
15       promoter, the metallothionein promoter, and fungal promoters such as, for example, the gal 4 promoter, the alcohol dehydrogenase promoter, the phosphoglycerol kinase promoter, and the mating factor promoters, to name just a few.

          Methods are well-known in the art for constructing recombinant vectors containing particular coding sequences in operative association with appropriate regulatory elements, and any of these can be used to practice the present invention. These methods include in  
20       vitro recombinant techniques, synthetic techniques, and in vivo genetic recombination. See, e.g., the techniques described in Maniatis et al., 1989, above; Ausubel et al., 1989, above; Sambrook et al., 1989, above; Innis et al., 1995, above; and Erlich, 1992, above.

          Fusion protein expression vectors can be used to express an MLK4, PAK4, PAK5 or  
25       YSK2 gene product-fusion protein. The purified fusion protein can be used to raise antisera against the MLK4, PAK4, PAK5 or YSK2 gene product, to study the biochemical properties of the MLK4, PAK4, PAK5 or YSK2 gene product, to engineer the MLK4, PAK4, PAK5 or YSK2 fusion proteins with different biochemical activities, or to aid in the identification or purification of the expressed MLK4, PAK4, PAK5 or YSK2 gene product in recombinant expression  
30       systems. Possible fusion protein expression vectors include but are not limited to vectors incorporating sequences that encode  $\beta$ -galactosidase and trpE fusions, maltose binding protein fusions, glutathione-S-transferase fusions and polyhistidine fusions (carrier regions).

          MLK4, PAK4, PAK5 or YSK2 fusion proteins can be engineered to comprise a region useful for purification. For example, MLK4-, PAK4-, PAK5- and YSK2-maltose-binding protein  
35       fusions can be purified using amylose resin; MLK4-, PAK4-, PAK5- and YSK2-glutathione-S-transferase fusion proteins can be purified using glutathione-agarose beads; and MLK4-, PAK4-, PAK5- and YSK2-polyhistidine fusions can be purified using divalent nickel resin.

Alternatively, antibodies against a carrier protein or peptide can be used for affinity chromatography purification of the fusion protein. For example, a nucleotide sequence coding for the target epitope of a monoclonal antibody can be engineered into the expression vector in operative association with the regulatory elements and situated so that the expressed epitope is fused to the MLK4, PAK4, PAK5 or YSK2 polypeptide. For example, a nucleotide sequence coding for the FLAG™ epitope tag (International Biotechnologies Inc.), which is a hydrophilic marker peptide, can be inserted by standard techniques into the expression vector at a point corresponding to the amino or carboxyl terminus of the MLK4, PAK4, PAK5 or YSK2 polypeptide. The expressed MLK4, PAK4, PAK5 or YSK2 polypeptide-FLAG™ epitope fusion product can then be detected and affinity-purified using commercially available anti-FLAG™ antibodies.

The expression vector encoding the MLK4, PAK4, PAK5 or YSK2 fusion protein can also be engineered to contain sequences that encode specific protease cleavage sites so that the expressed MLK4, PAK4, PAK5 or YSK2 polypeptide can be released from the carrier region or fusion partner by treatment with a specific protease. For example, the fusion protein vector can include DNA sequences encoding thrombin or factor Xa cleavage sites, among others.

A signal sequence upstream from and in reading frame with the MLK4, PAK4, PAK5 or YSK2 ORF can be engineered into the expression vector by known methods to direct the trafficking and secretion of the expressed gene product. Non-limiting examples of signal sequences include those from  $\alpha$  factor, immunoglobulins, outer membrane proteins, penicillinase, and T-cell receptors, among others.

To aid in the selection of host cells transformed or transfected with cloning or expression vectors of the present invention, the vector can be engineered to further comprise a coding sequence for a reporter gene product or other selectable marker. Such a coding sequence is preferably in operative association with regulatory element coding sequences, as described above. Reporter genes that can be useful in the invention are well known in the art and include those encoding green fluorescent protein, luciferase, xylE, and tyrosinase, among others. Nucleotide sequences encoding selectable markers are well known in the art, and include those that encode gene products conferring resistance to antibiotics or anti-metabolites, or that supply an auxotrophic requirement. Examples of such sequences include those that encode resistance to methotrexate, G418 or mycophenolic acid, among many others.

#### **5.3.2. Host Cells**

The present invention further provides transformed host cells comprising a polynucleotide molecule or recombinant vector of the invention, and novel strains or cell lines derived therefrom. Host cells useful in the practice of the invention are preferably human

cells, although other eukaryotic cells or prokaryotic cells can also be used. Such other transformed host cells typically include but are not limited to microorganisms, such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA vectors, or yeast transformed with recombinant vectors, among others.

- 5           Appropriate host cells can be chosen that modify and process the gene product in the specific fashion desired. Different host cells have characteristic mechanisms for the translational and post-translational processing and modification (e.g., glycosylation, phosphorylation) of proteins. For example, expression in a bacterial system can be used to produce an unglycosylated protein product. Expression and secretion in yeast can produce a
- 10           glycosylated protein product. Expression in mammalian cells can be used to ensure "native" processing of a protein product. Further, different vector/host expression systems can affect processing reactions to different degrees.

- Preferred bacterial cells as host cells are strains of *E. coli*, e.g., for cloning or expression purposes. A strain of *E. coli* adapted to growth in culture and for cloning
- 15           techniques can typically be used, such as, e.g., the DH5 $\alpha$  strain, which is available either from the American Type Culture Collection (ATCC), Rockville, MD, USA (Accession No. 31343) or from commercial sources (Stratagene). Preferred eukaryotic host cells include human cells, and in particular keratinocytes, although other mammalian cells and yeast cells or insect cells can also be utilized effectively.

- 20           The recombinant expression vector of the invention is preferably transformed or transfected into one or more host cells of a substantially homogeneous culture of cells. The expression vector is generally introduced into host cells in accordance with known techniques, such as, e.g., by protoplast transformation, calcium phosphate precipitation, calcium chloride treatment, microinjection, electroporation, transfection by contact with a
- 25           recombined virus, liposome-mediated transfection, DEAE-dextran transfection, transduction, conjugation, or microprojectile bombardment. Selection of transformants can be conducted by standard procedures, such as by selecting for cells expressing a selectable marker, e.g., antibiotic resistance, associated with the recombinant vector, as described above.

- Once the expression vector is introduced into the host cell, the integration and
- 30           maintenance of the MLK4-, PAK4-, PAK5- or YSK2-related coding sequence, either in the host cell chromosome or episomally, can be confirmed by standard techniques, e.g., by Southern hybridization analysis, restriction enzyme analysis, PCR analysis, including reverse transcriptase PCR (rt-PCR), or by immunological assay to detect the expected gene product. Host cells containing and/or expressing the recombinant MLK4-, PAK4-, PAK5- or YSK2-
- 35           related coding sequence can be identified by any of at least four general approaches which are well-known in the art, including: (i) DNA-DNA, DNA-RNA, or RNA-antisense RNA hybridization; (ii) detecting the presence of "marker" gene functions; (iii) assessing the level of

transcription as measured by the expression of MLK4-, PAK4-, PAK5- or YSK2-specific mRNA transcripts in the host cell; and (iv) detecting the presence of mature polypeptide product as measured, e.g., by immunoassay.

### **5.3.3. Expression And Characterization Of JNKKK Polypeptides**

5        Once the MLK4-, PAK4-, PAK5- or YSK2-related coding sequence has been stably introduced into an appropriate host cell, the transformed host cell is clonally propagated, and the resulting cells are grown under conditions conducive to the maximum production of the MLK4-, PAK4-, PAK5- or YSK2-related gene products. Such conditions typically include growing cells to high density. Where the expression vector comprises an inducible promoter, 10        appropriate induction conditions such as, e.g., temperature shift, exhaustion of nutrients, addition of gratuitous inducers (e.g., analogs of carbohydrates, such as isopropyl- $\beta$ -D—thiogalactopyranoside (IPTG)), accumulation of excess metabolic by-products, or the like, are employed as needed to induce expression.

Where the expressed MLK4-, PAK4-, PAK5- or YSK2-related gene product is 15        retained inside the host cells, the cells are harvested and lysed, and the product is isolated and purified from the lysate under extraction conditions known in the art to minimize protein degradation such as, e.g., at 4°C, or in the presence of protease inhibitors, or both. Where the expressed MLK4-, PAK4-, PAK5- or YSK2-related gene product is secreted from the host cells, the exhausted nutrient medium can simply be collected and the product isolated 20        therefrom.

The expressed MLK4-, PAK4-, PAK5- or YSK2-related gene product can be isolated or substantially purified from cell lysates or culture medium, as appropriate, using standard methods, including but not limited to any combination of the following methods: ammonium sulfate precipitation, size fractionation, ion exchange chromatography, HPLC, density 25        centrifugation, and affinity chromatography. Where the expressed MLK4-, PAK4-, PAK5- or YSK2-related gene products exhibit biological activity, increasing purity of the preparation can be monitored at each step of the purification procedure by use of an appropriate assay. Whether or not the expressed MLK4-, PAK4-, PAK5- or YSK2-related gene products exhibit biological activity, each can be detected as based, e.g., on size, or reactivity with an antibody 30        otherwise specific for MLK4, PAK4, PAK5 or YSK2, or by the presence of a fusion tag.

The present invention thus provides a substantially purified or isolated polypeptide encoded by a polynucleotide molecule of the present invention. In a specific though non-limiting embodiment, the polypeptide is a human MLK4 gene product, or a portion thereof, comprising the amino acid sequence of SEQ ID NO:2. In another specific though non-limiting 35        embodiment, the polypeptide is a human PAK4 gene product, or a portion thereof, comprising the amino acid sequence of SEQ ID NO:4. In still another specific though non-limiting embodiment, the polypeptide is a human PAK5 gene product, or a portion thereof, comprising

the amino acid sequence of SEQ ID NO:6, 8 or 10. In another specific though non-limiting embodiment, the polypeptide is a human YSK-2 gene product, or a portion thereof, comprising the amino acid sequence of SEQ ID NO:13. The present invention further provides substantially purified or isolated polypeptides that are homologous to any of the

5 MLK4, PAK4, PAK5 or YSK2 gene products of the present invention, as homologous polypeptides are defined above. The present invention further provides peptide fragments of the MLK4, PAK4, PAK5 or YSK2 gene products or homologous polypeptides of the present invention, as peptide fragments are defined above. The substantially purified or isolated polypeptides of the present invention are useful for a variety of purposes, such as, e.g.,

10 screening for compounds that interact with MLK4, PAK4, PAK5 or YSK2 proteins, and hence are candidates for compounds that affect MLK4, PAK4, PAK5 or YSK2 activity (including the events involved in signal transduction), and for raising antibodies directed against MLK4, PAK4, PAK5 or YSK2 gene product. Such compounds and antibodies can be used in therapeutic methods to treat or prevent UV damage to the skin.

15 As used herein, a polypeptide is "substantially purified" where the polypeptide constitutes the majority (i.e., at least about 50%) by weight of the material in a particular preparation. Also, as used herein, a polypeptide is "isolated" where the polypeptide constitutes at least about 90 wt% of the material in a particular preparation. Also, as used herein, a polynucleotide molecule is "isolated" where it constitutes at least about 90 wt% of

20 the nucleic acid material in a particular preparation, or where it appears to be separated from all other polynucleotide molecules as determined, e.g., by gel electrophoresis techniques.

The present invention further provides a method of preparing a substantially purified or isolated MLK4 gene product, PAK4 gene product, PAK5 gene product, YSK2 gene product or peptide fragment of the present invention, comprising culturing a host cell transformed or

25 transfected with a polynucleotide molecule or recombinant vector of the present invention, said recombinant vector comprising a polynucleotide molecule comprising a nucleotide sequence encoding the MLK4 gene product, PAK4 gene product, PAK5 gene product, YSK2 gene product or peptide fragment, respectively, of the present invention, wherein the nucleotide sequence is in operative association with one or more regulatory elements, under

30 conditions conducive to the expression of the particular gene product, polypeptide, or peptide fragment, and recovering the expressed gene product, polypeptide, or peptide fragment, from the cell culture in a substantially purified or isolated form.

Once an MLK4, PAK4, PAK5 or YSK2 gene product of sufficient purity has been obtained, it can be characterized by standard methods, including by SDS-PAGE, size

35 exclusion chromatography, amino acid sequence analysis, biological activity such as kinase activity, etc. For example, the amino acid sequence of the MLK4, PAK4, PAK5 or YSK2 gene product can be determined using standard peptide sequencing techniques. The MLK4,

PAK4, PAK5 or YSK2 gene product can be further characterized using hydrophilicity analysis (see, e.g., Hopp and Woods, 1981, Proc. Natl. Acad. Sci. USA 78:3824), or analogous software algorithms, to identify hydrophobic and hydrophilic regions of the MLK4, PAK4, PAK5 or YSK2 gene product respectively. Structural analysis can be carried out to identify regions of the MLK4, PAK4, PAK5 or YSK2 gene product that assume specific secondary structures. Biophysical methods such as X-ray crystallography (Engstrom, 1974, Biochem. Exp. Biol. 11:7-13), computer modeling (Eletterick and Zoller (eds), 1986, in: Current Communications in Molecular Biology, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY), and nuclear magnetic resonance (NMR) can be used to map and study sites of interaction between the MLK4, PAK4, PAK5 or YSK2 gene products and their substrates. Information obtained from these studies can be used to select specific sites on the MLK4, PAK4, PAK5 or YSK2 gene products as potential targets for drug candidates that interact with, and alter the activity of, these gene products.

#### **5.4. Antibodies**

The present invention further provides polyclonal and monoclonal antibodies that bind to an MLK4 gene product, PAK4 gene product, PAK5 gene product, YSK2 gene product, or to an homologous polypeptide or peptide fragment, of the present invention. Such antibodies can be used as affinity reagents with which to purify a native MLK4, PAK4, PAK5 or YSK2 gene product, or to analyze the activity or biological function of the MLK4, PAK4, PAK5 or YSK2 gene product.

Antibodies can be raised against any of the MLK4-, PAK4-, PAK5- or YSK2-related polypeptides of the present invention. Various host animals, including but not limited to cows, horses, rabbits, goats, sheep, and mice, can be used according to known methods to produce anti-MLK4, anti-PAK4, anti-PAK5 or anti-YSK2-specific antibodies. Various adjuvants known in the art can be used to enhance antibody production.

Polyclonal antibodies can be obtained from immunized animals and tested for anti-MLK4, anti-PAK4, anti-PAK5 or anti-YSK2 specificity using standard techniques. Alternatively, monoclonal antibodies to an MLK4, PAK4, PAK5 or YSK2 polypeptide can be prepared using any technique that provides for the production of antibody molecules by continuous cell lines in culture. These include but are not limited to the hybridoma technique originally described by Kohler and Milstein (Nature, 1975, 256: 495-497); the human B-cell hybridoma technique (Kosbor, et al., 1983, Immunology Today 4:72; Cote, et al., 1983, Proc. Natl. Acad. Sci. USA 80: 2026-2030); and the EBV-hybridoma technique (Cole, et al., 1985, Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77- 96). Alternatively, techniques described for the production of single chain antibodies (see, e.g., U.S. Patent 4,946,778) can be adapted to produce MLK4-, PAK4-, PAK5- or YSK2- specific single chain antibodies. These publications are incorporated herein by reference.

Antibody fragments that contain specific binding sites for an MLK4, PAK4, PAK5 or YSK2 polypeptide are also encompassed within the present invention and can be generated by known techniques. Such fragments include but are not limited to F(ab')<sub>2</sub> fragments, which can be generated by pepsin digestion of an intact antibody molecule, and Fab fragments, which can be generated by reducing the disulfide bridges of the F(ab')<sub>2</sub> fragments. Alternatively, Fab expression libraries can be constructed (Huse *et al.*, 1989, Science 246: 1275-1281) to allow rapid identification of Fab fragments having the desired specificity to the MLK4, PAK4, PAK5 or YSK2 polypeptide.

Techniques for the production of monoclonal antibodies and antibody fragments are well-known in the art, and are additionally described, among other places, in Harlow and Lane, 1988, Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory; and in J. W. Goding, 1986, Monoclonal Antibodies: Principles and Practice, Academic Press, London. All of the above-cited publications are incorporated herein by reference.

#### **5.5. Anti-sense Oligonucleotides And Ribozymes**

Also within the scope of the present invention are oligonucleotide sequences that include anti-sense oligonucleotides, phosphorothioates and ribozymes that function to bind to, degrade and/or inhibit the translation of MLK4, PAK4, PAK5 or YSK2 mRNA.

Anti-sense oligonucleotides, including anti-sense RNA molecules and anti-sense DNA molecules, act to directly block the translation of mRNA by binding to targeted mRNA and preventing protein translation. For example, antisense oligonucleotides of at least about 15 bases and complementary to unique regions of the DNA sequence encoding an MLK4, PAK4, PAK5 or YSK2 polypeptide can be synthesized, e.g., by conventional phosphodiester techniques.

Ribozymes are enzymatic RNA molecules capable of catalyzing the specific cleavage of RNA. The mechanism of ribozyme action involves sequence specific hybridization of the ribozyme molecule to complementary target RNA, followed by endonucleolytic cleavage. Engineered hammerhead motif ribozyme molecules that specifically and efficiently catalyze endonucleolytic cleavage of MLK4, PAK4, PAK5 or YSK2 mRNA sequences are also within the scope of the present invention.

Specific ribozyme cleavage sites within any potential RNA target are initially identified by scanning the target molecule for ribozyme cleavage sites that include the following sequences, GUA, GUU, and GUC. Once identified, short RNA sequences of between about 15 and 20 ribonucleotides corresponding to the region of the target gene containing the cleavage site can be evaluated for predicted structural features such as secondary structure that may render the oligonucleotide sequence unsuitable. The suitability of candidate targets can also be evaluated by testing their accessibility to hybridization with complementary oligonucleotides using, e.g., ribonuclease protection assays.

Both the anti-sense oligonucleotides and ribozymes of the present invention can be prepared by known methods. These include techniques for chemical synthesis such as, e.g., by solid phase phosphoamide chemical synthesis. Alternatively, anti-sense RNA molecules can be generated by in vitro or in vivo transcription of DNA sequences encoding the RNA molecule. Such DNA sequences can be incorporated into a wide variety of vectors that incorporate suitable RNA polymerase promoters such as the T7 or SP6 polymerase promoters.

Various modifications to the oligonucleotides of the present invention can be introduced as a means of increasing intracellular stability and half-life. Possible modifications include but are not limited to the addition of flanking sequences of ribonucleotides or deoxyribonucleotides to the 5' and/or 3' ends of the molecule, or the use of phosphorothioate or 2'-O-methyl rather than phosphodiesterase linkages within the oligonucleotide backbone.

#### **5.6. Detection Of JNKKK Gene Products, And Diagnostic And Therapeutic Uses**

The MLK4, PAK4, PAK5 and YSK2 polynucleotide molecules, oligonucleotides, and polypeptides of the present invention, as well as antibodies of the present invention that recognize the MLK4, PAK4, PAK5 or YSK2 polypeptides, are useful in the diagnosis of diseases or conditions resulting from alteration in the expression of MLK4, PAK4, PAK5 or YSK2 gene products. Alteration in expression can be either an increase or decrease in transcription of the MLK4, PAK4, PAK5 or YSK2 gene, or an increase or decrease in translation of an MLK4, PAK4, PAK5 or YSK2 gene product. Alternatively, the presence of mutations, alleles, or polymorphisms in the MLK4, PAK4, PAK5 or YSK2 gene sequence can be correlated with diseases or conditions, including but not limited to increased or decreased susceptibility to skin damage caused by ultraviolet light or other stresses, or psoriasis.

Nucleic acid-based detection methods are well known in the art and include hybridization assays (e.g., Northern and Southern hybridizations, nuclease protection), polymerase chain reaction (PCR) assays, and ligation chain reaction (LCR) assays, or combinations of the above (e.g., in situ hybridization). Such assays make use of the MLK4, PAK4, PAK5 or YSK2 polynucleotides and oligonucleotides of the present invention, including complementary sequences, as described above. If analysis of an RNA gene product is desired, certain assays would typically include a reverse transcription step prior to amplification and/or hybridization, as known in the art. Such nucleic acid based techniques can be designed by those of ordinary skill in the art to assay the levels of MLK4, PAK4, PAK5 or YSK2 gene expression, or the presence or absence of particular mutations, alleles or polymorphisms.

Protein or polypeptide-based detection methods are also well known to those of ordinary skill and include, e.g., immunological assays such as Western blot, immunoprecipitation of labeled target, and ELISA assays. These assays use the antibodies

of the present invention described above. Again, such assays can measure levels of MLK4, PAK4, PAK5 or YSK2 polypeptides expressed by a cell or organism, or the presence of mutants, alleles, or polymorphisms in the MLK4, PAK4, PAK5 or YSK2 polypeptides.

If an abnormal condition is associated with the over- or under-production of an MLK4, PAK4, PAK5 or YSK2 gene product, the polynucleotides and oligonucleotides of the invention can be useful in preventing, ameliorating or otherwise treating of the abnormal condition. For example, by introducing gene sequences into cells, gene therapy can be used to treat conditions in which the cells express inadequate levels of MLK4, PAK4, PAK5 or YSK2 gene product, or express abnormal or inactive MLK4, PAK4, PAK5 or YSK2 polypeptides. In some instances, abnormal conditions characterized by over-expression of MLK4, PAK4, PAK5 or YSK2 gene product can be prevented or treated using the gene therapy techniques described below. Specifically, gene therapy vectors can be designed to express anti-sense polynucleotides or ribozymes of the present invention as described above, thereby reducing the amount of MLK4, PAK4, PAK5 or YSK2 gene products that are effectively translated into polypeptide.

Expression vectors derived from viruses such as retroviruses, vaccinia virus, adeno-associated virus, herpes viruses, or papilloma virus can be used for delivery of recombinant MLK4, PAK4, PAK5 or YSK2 polynucleotides into the targeted cell population. Methods that are well known to those skilled in the art can be used to construct recombinant viral vectors containing an MLK4, PAK4, PAK5 or YSK2 polynucleotide. See, for example, the techniques described in Maniatis et al., 1989, Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory, N.Y.; and Ausubel et al., 1989, Current Protocols in Molecular Biology, Greene Publishing Associates and Wiley Interscience, N.Y. Alternatively, recombinant, non-viral vectors containing an MLK4, PAK4, PAK5 or YSK2 polynucleotide can be reconstituted into liposomes for delivery to target cells, or can be delivered as a naked polynucleotide, such as, e.g., in a "DNA Vaccine," to name just a few examples.

#### **5.7. Drug Screening Applications**

MLK4, PAK4, PAK5 and YSK2 gene products, including polynucleotides, oligonucleotides and polypeptides, can be used in screening assays to identify compounds that specifically bind to MLK4, PAK4, PAK5 or YSK2 gene products and thus have potential use as agonists or antagonists of MLK4, PAK4, PAK5 or YSK2 polypeptides, respectively. In a particular preferred use, the polynucleotides and polypeptides of the invention are useful to screen for compounds that affect the kinase activities of MLK4, PAK4, PAK5 or YSK2 polypeptides.

The invention thus provides assays to detect molecules that specifically bind to MLK4, PAK4, PAK5 or YSK2 polypeptides. For example, recombinant cells expressing an MLK4, PAK4, PAK5 or YSK2 polynucleotide can be used to recombinantly produce an MLK4,

PAK4, PAK5 or YSK2 polypeptide, respectively, and to screen for molecules that bind to an MLK4, PAK4, PAK5 or YSK2 polypeptide, respectively. Methods that can be used to carry out the foregoing are commonly known in the art.

5 Diversity libraries, such as random or combinatorial peptide or non-peptide libraries can be screened for molecules that specifically bind to an MLK4, PAK4, PAK5 or YSK2 polypeptide. Many libraries are known in the art that can be used such as, e.g., chemically synthesized libraries, recombinant (e.g., phage display) libraries, and in vitro translation-based libraries.

10 Examples of chemically synthesized libraries are described in Fodor et al., 1991, Science 251:767-773; Houghten et al., 1991, Nature 354:84-86; Lam et al., 1991, Nature 354:82-84; Medynski, 1994, Bio/Technology 12:709-710; Gallop et al., 1994, J. Medicinal Chemistry 37(9):1233-1251; Ohlmeyer et al., 1993, Proc. Natl. Acad. Sci. USA 90:10922-10926; Erb et al., 1994, Proc. Natl. Acad. Sci. USA 91:11422-11426; Houghten et al., 1992, Biotechniques 13:412; Jayawickreme et al., 1994, Proc. Natl. Acad. Sci. USA 91:1614-1618; 15 Salmon et al., 1993, Proc. Natl. Acad. Sci. USA 90:11708-11712; PCT Publication No. WO 93/20242, dated October 14, 1993; and Brenner and Lerner, 1992, Proc. Natl. Acad. Sci. USA 89:5381-5383.

20 Examples of phage display libraries are described in Scott and Smith, 1990, Science 249:386-390; Devlin et al., 1990, Science, 249:404-406; Christian, R.B. et al., 1992, J. Mol. Biol. 227:711-718; Lenstra, 1992, J. Immunol. Meth. 152:149-157; Kay et al., 1993, Gene 128:59-65; and PCT Publication No. WO 94/18318, dated August 18, 1994.

In vitro translation-based libraries include but are not limited to those described in PCT Publication No. WO 91/05058, dated April 18, 1991; and Mattheakis et al., 1994, Proc. Natl. Acad. Sci. USA 91:9022-9026.

25 In one example, non-peptide libraries, such as a benzodiazepine library (see e.g., Bunin et al., 1994, Proc. Natl. Acad. Sci. USA 91:4708-4712), can be screened. Peptoid libraries, such as that described by Simon et al., 1992, Proc. Natl. Acad. Sci. USA 89:9367-9371, can also be used. Another example of a library that can be used, in which the amide functionalities in peptides have been permethylated to generate a chemically transformed 30 combinatorial library, is described by Ostresh et al. (1994, Proc. Natl. Acad. Sci. USA 91:11138-11142).

Screening the libraries can be accomplished by any of a variety of commonly known methods. See, for example, the following references, which disclose screening of peptide 35 libraries: Parmley and Smith, 1989, Adv. Exp. Med. Biol. 251:215-218; Scott and Smith, 1990, Science 249:386-390; Fowlkes et al., 1992, BioTechniques 13:422-427; Oldenburg et al., 1992, Proc. Natl. Acad. Sci. USA 89:5393-5397; Yu et al., 1994, Cell 76:933-945; Staudt et al., 1988, Science 241:577-580; Bock et al., 1992, Nature 355:564-566; Tuerk et al., 1992,

Proc. Natl. Acad. Sci. USA 89:6988-6992; Ellington et al., 1992, Nature 355:850- 852; U.S. Patent No. 5,096,815, U.S. Patent No. 5,223,409, and U.S. Patent No. 5,198,346, all to Ladner et al.; Rebar and Pabo, 1993, Science 263:671-673; and PCT Publication No. WO 94/18318.

5           In a specific embodiment, screening can be carried out by contacting the library members with an MLK4, PAK4, PAK5 or YSK2 polypeptide immobilized on a solid phase and harvesting those library members that bind to the polypeptide. Examples of such screening methods, termed "panning" techniques, are described by way of example in Parmley and Smith, 1988, Gene 73:305-318; Fowlkes et al., 1992, BioTechniques 13:422- 427; PCT  
10       Publication No. WO 94/18318; and in other references cited hereinabove.

          In another embodiment, the two-hybrid system for selecting interacting proteins in yeast (Fields and Song, 1989, Nature 340:245-246; Chien et al., 1991, Proc. Natl. Acad. Sci. USA 88:9578-9582) can be used to identify molecules that specifically bind to an MLK4, PAK4, PAK5 or YSK2 polypeptide within a cell.

15           In another aspect of the invention, methods for screening candidate compounds for drugs are provided. Such drugs can be used to reduce ultraviolet light-induced damage, inflammation and psoriasis, and enhance wound healing in a subject. The subject is an animal, typically a mammal, preferably a human.

          For example, one can screen for compounds that affect the expression of an MLK4,  
20       PAK4, PAK5 or YSK2 gene product of the present invention by: (a) applying a test compound to a test sample; (b) determining the expression of at least one MLK4, PAK4, PAK5 or YSK2 gene product in the test sample; and (c) comparing the expression of the gene in the test sample with that in a reference sample. A specific change in the cellular level of the gene product in the test sample as compared to the reference sample indicates that the compound  
25       affects the cellular level of gene product from a JNKKK gene. By the term "a specific change in the cellular level of the gene product" is meant that the change in level occurs without alteration of overall transcription or translation levels in the cell (depending upon the gene product assayed). For example, when mRNA is measured, a compound that causes a  
"specific change" is not a compound that is a general transcriptional repressor. Similarly, for  
30       example, when protein levels are assayed, a compound that causes a "specific change" is not a general translational repressor. One can determine whether global effects on transcription or translation occur in the presence of a test compound by assaying for a control housekeeping gene product (e.g., glucose-6- phosphate dehydrogenase gene product or the actin gene product, to name just two examples).

35           One can also assay the effect of a test compound on the expression or cellular response of the MLK4, PAK4, PAK5 or YSK2 gene or polypeptide in the presence of, or in response to, a stress event. The stress event applied to the cells can be exposure to

ultraviolet radiation. Preferred ultraviolet radiation can be UV-A with a wavelength in the range of 320-400 nm, or UV-B with a wavelength in the range of 280-320 nm, or UV-C with a wavelength in the range of 200-280 nm. Other types of stress events applied to the sample for screening purposes can be exposure to inflammatory cytokines such as TNF- $\alpha$ , IL-1, interferons, FGFs or PDGF. Still other types of stress events are heat shock, osmotic shock, exposure to toxic chemicals such as arsenic, disruption of the permeability barrier (e.g., with solvents), etc.

In one preferred embodiment, the method of drug screening comprises: (a) applying a test compound to a test sample; (b) exposing the test sample and a reference sample to a stress event; (c) determining the expression of at least one gene product in the test sample, wherein the transcript of the gene product comprises a sequence selected from the group consisting of SEQ ID NOS: 1, 3, 5, 7, 9, 11 and 12; and (d) determining the effectiveness of the test compound in blocking or otherwise modulating the cellular response to the stress event by comparing the expression of the gene product in the test sample with that in the reference sample. If the test compound significantly reduces the expression of the transcript in response to the stress event, the test compound is identified as a drug candidate that may be potentially effective in blocking the cellular response to the stress event. The expression of the MLK4, PAK4, PAK5 or YSK2 gene product can be determined using any of the methods described above. The most preferred gene products for use in this assay are the PAK5 and YSK2 gene products.

In another preferred embodiment, the method of drug screening entails: (a) applying a test compound to a test sample; (b) applying a stress event to the test sample; and (c) determining the amount of an MLK4, PAK4, PAK5 or YSK2 polypeptide in the test sample and in a reference sample, wherein the MLK4, PAK4, PAK5 or YSK2 polypeptide comprises an amino acid sequence selected from the group consisting of: SEQ ID NOS: 2, 4, 6, 8, 10 and 13; wherein a reduction in the amount of the MLK4, PAK4, PAK5 or YSK2 polypeptide in the test sample as compared to that in the reference sample indicates that the test compound is identified as a drug candidate that can potentially block the stress response.

Still another aspect of the invention is a method of screening for compounds that affect the activity of an MLK4, PAK4, PAK5 or YSK2 polypeptide. One can apply a test compound to a test sample and determine the activity of the MLK4, PAK4, PAK5 or YSK2 polypeptide in the test sample compared to that in a reference sample. A test compound that alters the MLK4, PAK4, PAK5 or YSK2 polypeptide activity in the test sample as compared to the reference sample is identified as a drug candidate that can potentially affect the activity of the MLK4, PAK4, PAK5 or YSK2 polypeptide. Each of the full-length MLK4, PAK4, PAK5 and YSK2 polypeptides is a kinase; thus, the activities of these polypeptides include kinase activity and binding to ATP and its analogs. Other activities include the ability to interact with

activators that activate MLK4, PAK4, PAK5 or YSK2 polypeptide kinase activity, interaction with downstream target proteins, and interaction with inhibitors via the amino-terminal regulatory domain.

In another preferred embodiment, the activity of MLK4, PAK4, PAK5 or YSK2 polypeptides, such as kinase activity, binding to ATP and its analogs, or activation of downstream target protein, can be assayed in the test and reference samples in response to application of a stress event, and compared, to predict the effectiveness of the drug candidate. If the drug candidate prevents the induction of the function of the MLK4, PAK4, PAK5 or YSK2 polypeptide by a particular stress event, such as ultraviolet radiation, the drug candidate can be effective at blocking the stress response.

In some preferred embodiments, the test and reference samples are cultured cells, tissues or organs. In other preferred embodiments, the test and reference samples are live animals. In a particularly preferred embodiment, a small biopsy of human skin (e.g., about 5 mm<sup>3</sup>) is placed in culture and treated with, e.g., ultraviolet radiation, one or more growth factors, cytokines, drugs, hormones or vitamins. After a defined period of time (typically 24-48 hours when the treatment is ultraviolet radiation), the biopsy is tested for expression of the MLK4, PAK4, PAK5 or YSK2 gene product, or for activity of the MLK4, PAK4, PAK5 or YSK2 polypeptide.

The invention having been described, the following examples are offered by way of illustration and not limitation.

## **6. Example: Cloning Of The YSK2, MLK4, PAK4 And PAK5 cDNAs**

This example illustrates the methods used to clone the novel JNKKs of the invention.

### **6.1. Materials And Methods**

Normal human foreskin epidermal keratinocytes were a generous gift from Dr. M. Simon of the State University of New York at Stony Brook. The cultures were initiated using 3T3 feeder layers and then frozen in liquid nitrogen until used. Once thawed, the keratinocytes were grown without feeder cells in defined serum-free keratinocyte growth medium (KGM), supplemented with bovine pituitary extract epidermal growth factor, insulin, thyroid hormone and hydrocortisone (keratinocyte-SFM, GIBCO).

Messenger RNA from the keratinocytes was used for reverse transcription polymerase chain reaction (RT-PCR) amplification with an RT-PCR kit (Promega Corp., Madison, Wisconsin). Primers corresponding to regions of homology between the kinase domains of JNKKs or JNKKs were designed to amplify a 150 bp PCR products from keratinocyte mRNA using RT-PCR. The primers contain the following sequences that correspond to the regions of the kinase domain.

Forward: 5'-ATGCA(CA)CANGA(CT)AT(ACT)AA(AG)-3' (SEQ ID NO:14)

Reverse: 5'-GCNAC(CT)TCNGGNGCCATCCA-3' (SEQ ID NO:15)

The actual primers used for RT-PCR also contained cloning sites. Their sequences are as follows:

Forward: 5'-CCCGAATTCATGCA(CA)CANGA(CT)AT(ACT)AA(AG)-3'  
(SEQ ID NO:16)

Reverse: 5'-CCCGAATTCGCNAC(CT)TCNGGNGCCATCCA-3'  
(SEQ ID NO: 17)

The PCR products were sub-cloned and sequenced.

## 6.2. Results

Among the seventy different clones sequenced, ten different JNKKKs were identified, four of which appeared to be novel. An amino acid sequence comparison against the protein databases in the European Molecular Biology Network (available at <http://www.expasy.ch>; <http://www.expasy.ch>; <http://www.ch.embnet.org>) with other JNKKKs revealed that the four novel JNKKKs exhibited some degree of homology to various known JNKKKs from several different families. One JNKKK clone was 91% identical at positions 12-131 to a 134 base region of the murine YSK2 gene sequence (corresponding to positions 503-384 of emb: U49949, Osada et al., 1997, Oncogene 14:2047-2057); hence, this clone was designated as the human keratinocyte YSK2 (SEQ ID NO:12). Additionally, two human expressed sequence tags (ESTs) were related to the human keratinocyte YSK2. Specifically, Human EST emb:AA557573 (NCI-CGAP, "National Cancer Institute, Cancer Genome Anatomy Project (CGAP), Tumor Gene Index <http://www.ncbi.nlm.nih.gov/ncicgap>," Unpublished.) showed a 96% identity with the human YSK2 gene sequence (SEQ ID NO:12) in a 137 bp region corresponding to positions 6-142 of SEQ ID NO:12 and positions 32-168 of emb:AA557573. Human EST emb:AA578088 (NCI-CGAP, "National Cancer Institute, Cancer Genome Anatomy Project (CGAP), Tumor Gene Index <http://www.ncbi.nlm.nih.gov/ncicgap>," Unpublished.) also showed a 96% identity with the SEQ ID NO:12 in a 136 bp region corresponding to positions 6-141 of SEQ ID NO:12 and positions 35-170 of emb:AA578088.

Another JNKKK clone, designated MLK4 (SEQ ID NO:1), was 50% to 78% identical to members of the MLK family of JNKKKs. Finally, two JNKKK clones, designated PAK4 (SEQ ID NO:3) and PAK5 (SEQ ID NO:5), showed similar identity to members of the PAK family of JNKKKs. However, no homolog sequences could be found in the European Molecular Biology Network protein database for either MLK4 or PAK5. Although initial sequence searches of PAK4 indicated it was a new member of the PAK gene family, during the course of this work, the complete sequence of human PAK4 was published (Abo et al., 1998, EMBO J 22:6527-6540).

The relative abundance of the different identified JNKKKs is shown below in TABLE 1 below.

**Table 1**  
**ABUNDANCE OF DIFFERENT JNKKKs**

Kinase	Number of Isolates
BPAG1*	1
GCK	3
LIMK	1
MEKK3	4
MLK4	2
NiK	94
PAK1	40
PAK2	31
PAK4	69
PAK5	59
YSK1	1
Ysk2	51
<b>Total</b>	<b>356</b>

\*LIMK is a protein kinase, related to, but not a member of, the JNKKK family.

- 5 Frangiskakis et al., 1996, Cell 86:59-69. BPAG1 is an abundant protein in basal keratinocytes. Its mRNA contains two segments recognized by the 8 bases at the 3' termini of our oligonucleotides.

The RT-PCR products (SEQ ID NOS:1, 3, 5, 12) of the MLK4, PAK4, PAK5 and YSK2 mRNAs were used as probes for Northern Hybridization to mRNAs from heart, brain, placenta, lung, liver, skeletal muscle, kidney and pancreas. Figure 2 shows that the expression of the PAK4 gene is ubiquitous among the organs tested. However, the PAK5 gene is strongly expressed in keratinocytes and in the brain, but not expressed, or only weakly expressed, in placenta, lung, liver, skeletal muscle, kidney and pancreas. The MLK4 gene is expressed in keratinocytes, kidney and pancreas, but not in the brain, placenta, lung, liver, and skeletal muscle. The size of the transcripts of PAK4, PAK5 and MLK4 are 3.4, 4.4 and 4.8 kb, respectively.

#### **7. Example: Genomic Sequence Of The PAK5 Gene**

Oligonucleotides 5'-GAGTGACTCCATCCTGC-3' (SEQ ID NO: 18) and 5'-GTAGGGGGTTCACCA-3' (SEQ ID NO: 19) were used to identify a genomic clone from a commercially available P1 human library (Genome Systems, Inc., St. Louis, MO) that contained the PAK5 gene. The P1 genomic clone was partially sequenced, and additional coding sequence deduced. The polynucleotide sequence, with deduced exons indicated, is presented as SEQ ID NO:7. SEQ ID NO:8 presents the deduced amino acid sequence from

20

the partial genomic sequence. A partial schematic structure of the PAK5 gene is depicted in Figure 1. A PLC-2 gene was found to be linked to the PAK5 gene in the P1 clone. The PLC-2 gene has been mapped to chromosome 15; thus, the PAK5 gene also must reside on chromosome 15.

5           The deduced amino acid sequence of the PAK5 protein (SEQ ID NO:8) is very similar to that of PAK4 (SEQ ID NO:4), especially in the kinase domain (amino acid residues 93 to 311 in SEQ ID NO:8). The kinase domains of any of the JNKKKs of the present invention have utility as enzymatically active domains to phosphorylate substrates. The sequence of the PAK5 kinase domain contains a conserved lysine (K) residue that is essential for ATP  
10           binding (amino acid residue 120 in SEQ ID NO:8). By analogy with PAK4, mutations that change this lysine residue in PAK5 to alanine or methionine residues will abolish PAK5 enzymatic activity, while mutations that change the lysine residue to a glutamine will make a full length PAK5 protein constitutively active. Less homology between PAK4 and PAK5 is observed outside of the kinase domain. The 21 residue carboxy terminal extension of PAK5  
15           is 4 amino acids longer than that of PAK4. Additionally, the available amino terminal sequences of the PAK5 protein bear no similarity to any known protein other than PAK4. Thus, both the carboxy terminal and the amino terminal regions of the PAK5 protein will be particularly useful in generating antibodies that immunospecifically recognize PAK5.

          The ORF of the complete human cDNA sequence of PAK5 is presented in SEQ ID  
20           NO:9 from nt 199-2244. The complete DNA sequence for the human PAK5 gene is presented in SEQ ID NO:10, with the ORF from nt 6125-17433.

#### **8. Example: Ultraviolet Radiation-Induced Expression Of YSK2 And PAK5 mRNA**

          In this example, the effect of various wavelengths of ultraviolet radiation on the expression of the novel JNKKKs was investigated. The effects of both UV-C light (short  
25           wavelength ultraviolet radiation of 220 to 290 nm) and UV-A light ( long wavelength ultraviolet radiation of 320 to 400 nm) were separately analyzed.

          Keratinocytes were grown as described in Section 6.1, above. The cells were expanded through two 1:4 passages before illumination with 3-10 mJ/cm<sup>2</sup> of UV-C light or 1-5 J/cm<sup>2</sup> of UV-A light. Cells were harvested 6 or 24 hours after exposure. PolyA mRNA was  
30           purified from the cells using kits from Qiagen.

          Figure 3A shows that the YSK2 gene is induced by UV-C light. Keratinocytes were exposed to 10 mJ/cm<sup>2</sup> of UV-C light. Messenger RNAs from control and UV-C light- treated cells were separated by electrophoresis and transferred to a membrane by Northern blotting. The membrane was then hybridized using the 190 bp YSK2 RT-PCR product labeled with  
35           <sup>32</sup>P-dNTPs as the probe. As Figure 3A shows, the expression of the YSK2 gene in keratinocytes was greatly enhanced by UV-C light exposure.

          Figure 3B shows that the PAK5 gene is induced by UV-A light treatment. Human

keratinocytes were exposed to UV-A light (5 mJ/cm<sup>2</sup>), harvested, and mRNA prepared from the cells. The levels of PAK4 and PAK5 mRNA in treated and untreated cells were compared using differential display. Liang and Pardee, 1992, Science 257:967-71. Amplification was performed using primer SEQ ID NOS:14 and 15, or SEQ ID NO:16 and 17, above. The resulting amplified DNA was then digested with restriction enzyme TaqI to reveal specifically the PAK4 and the PAK5 DNAs. The results demonstrate that PAK5 is induced by ultraviolet radiation.

Differential display experiments (Figures 3A and 3B) show that expression of both YSK2 and PAK5 genes are induced by ultraviolet radiation. However, induction of the two genes is dependent upon the wavelength of the ultraviolet radiation. YSK2 gene expression is induced by UV-C, which is the short wavelength ultraviolet radiation (220 to 290 nm). In contrast, the PAK5 gene expression is induced by UV-A, which is the long wavelength ultraviolet radiation (320 to 400 nm). The induction of YSK2 and PAK5 gene expression by ultraviolet radiation suggests that the products of the two genes are involved in the signal transduction cascade that transduces extracellular ultraviolet radiation (or other stress signals). Although MLK4 and PAK4 mRNA gene expression were not induced by ultraviolet radiation in these experiments, this fact cannot rule out a role in the keratinocyte response to light or other stresses. These gene products can be involved in the early cellular events in response to stress prior to any changes in gene expression.

The foregoing written specification is sufficient to enable one skilled in the art to practice the invention. Indeed, various modifications of the above-described means for carrying out the invention which are obvious to those skilled in the field of molecular biology, medicine or related fields are intended to be within the scope of the following claims.
